Centralized all-in-one cloud solution

We, at Eltima Software, are fans of all-in-one utilities combining many features and services in a simple manner. CloudMounter is the latest addition to our Mac OS X software family.

In the days of affordable high-speed unlimited Internet connection and low-capacity SSD drives in personal MacBooks, cloud storage services are becoming more and more popular. There is no need to always carry removable disks to transfer information from one location to another and no need to keep all your data on local drives. Simply upload your files to cloud server, and access them whenever needed even from a mobile device with fast mobile Internet connection or free Wi-Fi.

And with all the choices we have now it is not uncommon to have a number of different cloud accounts. This is where it becomes pretty handy to be able to manage all your clouds from a single point of access.

CloudMounter is our all-in-one solution for these purposes. This handy system utility allows mounting any number of cloud accounts on your Mac OS X as regular local disks or network shares.
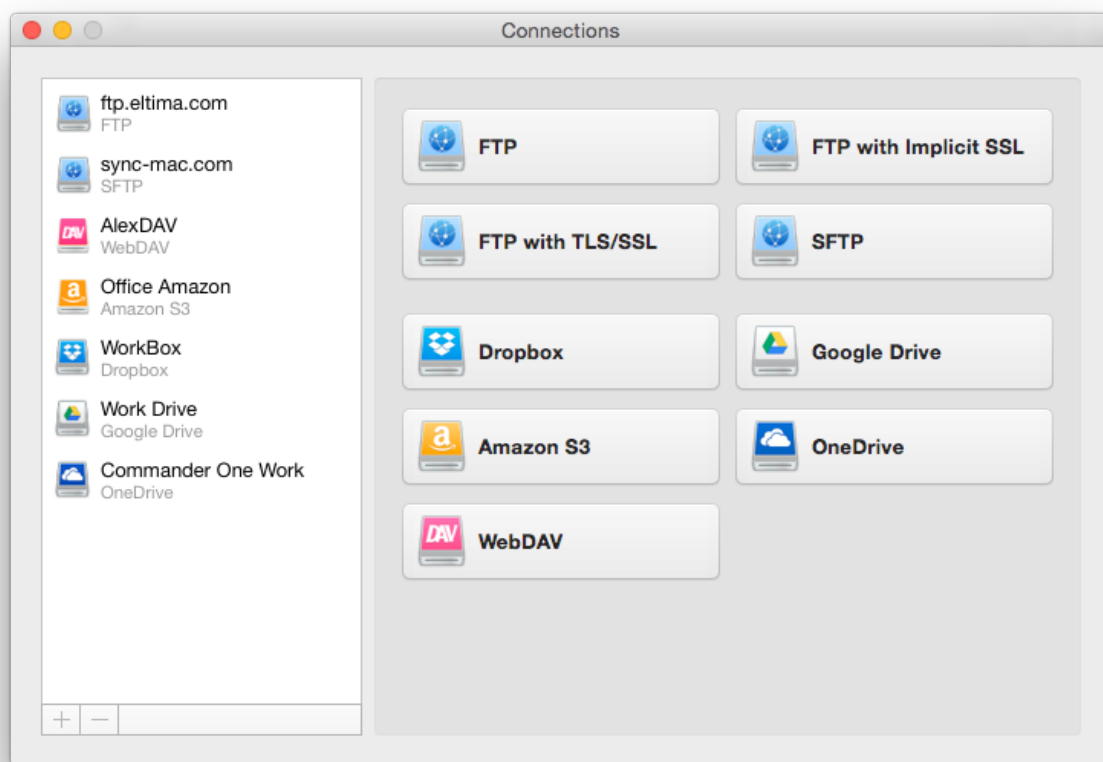

Get access to your online files - view, edit, delete, create, as well as upload to and download files from your remote server or cloud storage.

Connect and Manage

CloudMounter allows mounting any number of accounts of the following services:

- Google Drive
- Microsoft OneDrive
- Amazon S3
- Dropbox
- FTP, FTPS and SFTP servers
- WebDAV servers

We are constantly searching for the possible methods to expand the supported cloud resources and are already working to include several more in the nearest future.

Intuitive and Simple

The way it works is really simple. Main window of the app is basically a connections manager with corresponding buttons for each supported service and protocol. Just choose what you want to connect, enter your login credentials and enjoy managing your online files on a mounted drive in Finder.

Security and Privacy

CloudMounter does not store your login details. Access to cloud services is performed through their developers' API, and FTP\WebDAV passwords are securely kept in Mac OS X Keychain and sent directly to the servers via SSL-encrypted channels.
